Homework 6

References

- Lectures 21-23 (inclusive).

Instructions

- Type your name and email in the "Student details" section below.
- Develop the code and generate the figures you need to solve the problems using this notebook.
- For the answers that require a mathematical proof or derivation you should type them using latex. If you have never written latex before and you find it exceedingly difficult, we will likely accept handwritten solutions.
- The total homework points are 100. Please note that the problems are not weighed equally.

If on Google Colab, install the following packages:

Problem 1 - Defining priors on function spaces

In this problem, we will explore further how Gaussian processes can be used to define probability measures over function spaces. To this end, assume that there is a 1D function, call if $f(x)$, which we do not know. For simplicity, assume that x takes values in $[0, 1]$. We will employ Gaussian process regression to encode our state of knowledge about $f(x)$ and sample some possibilities. For each of the cases below:

- Assume that $f \sim \mathrm{GP}(m, k)$ and pick a mean ($m(x)$) and a covariance function $f(x)$ that match the provided information.

- Write code that samples a few times (up to five) the values of $f(x)$ at 100 equidistant points between 0 and 1.

Part A - Super smooth function with known length scale

Assume that you hold the following beliefs

- You know that $f(x)$ has as many derivatives as you want and they are all continuous
- You don't know if $f(x)$ has a specific trend.
- You think that $f(x)$ has "wiggles" that are approximatly of size $\Delta x = 0.1$.
- You think that $f(x)$ is between -4 and 4.

Answer:

I am doing this for you so that you have a concrete example of what is requested.

The mean function should be:

$$m(x) = 0.$$

The covariance function should be a squared exponential:

$$k(x, x') = s^2 \exp\left\{-\frac{(x - x')^2}{2\ell^2}\right\},$$

with variance:

$$s^2 = k(x, x) = \mathbb{V}[f(x)] = 4,$$

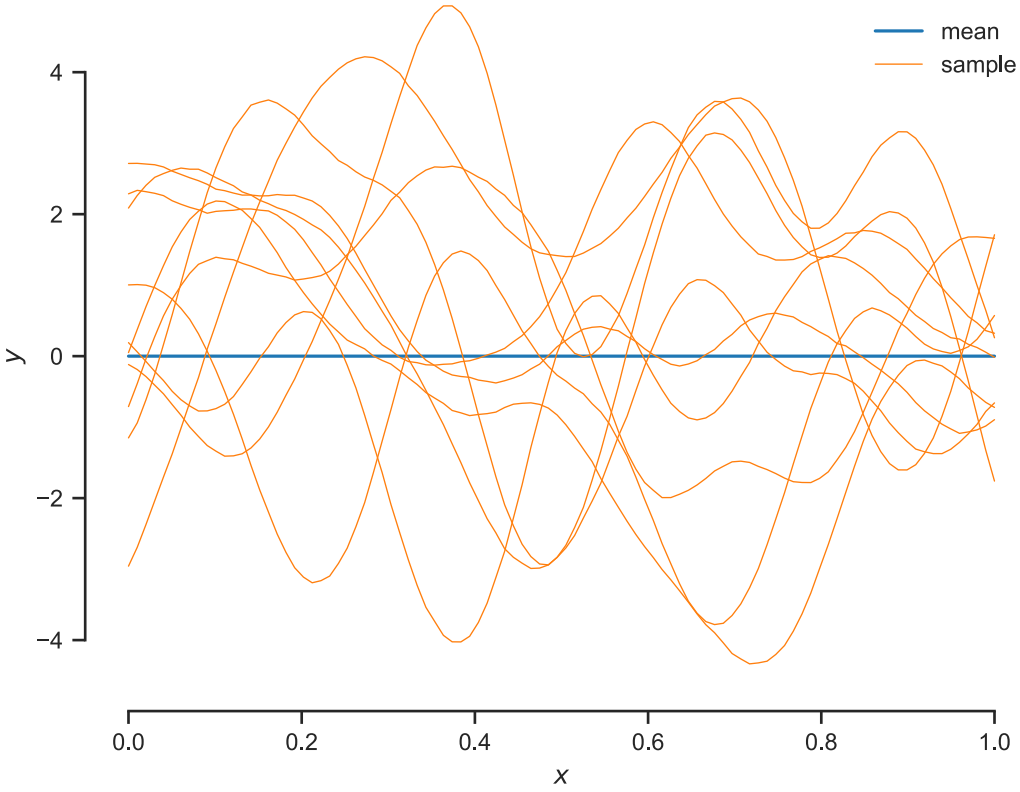
and lengthscale $\ell = 0.1$. We chose the variance to be 4.0 so that with (about) 95% probability, the values of $f(x)$ are between -4 and 4.

In [ ]:
```
import torch
import gpytorch
from gpytorch.kernels import RBFKernel, ScaleKernel

# Define the covariance function
k = ScaleKernel(RBFKernel())
k.outputscale = 4.0
k.base_kernel.lengthscale = 0.1

# Define the mean function
mean = gpytorch.means.ConstantMean()
mean.constant = 0.0

# Sample functions
sample_functions(mean, k, nugget=1e-4)
```



Part B - Super smooth function with known ultra-small length scale

Assume that you hold the following beliefs

- You know that $f(x)$ has as many derivatives as you want and they are all continuous
- You don't know if $f(x)$ has a specific trend.
- You think that $f(x)$ has "wiggles" that are approximatly of size $\Delta x = 0.05$.
- You think that $f(x)$ is between -3 and 3.

Answer:

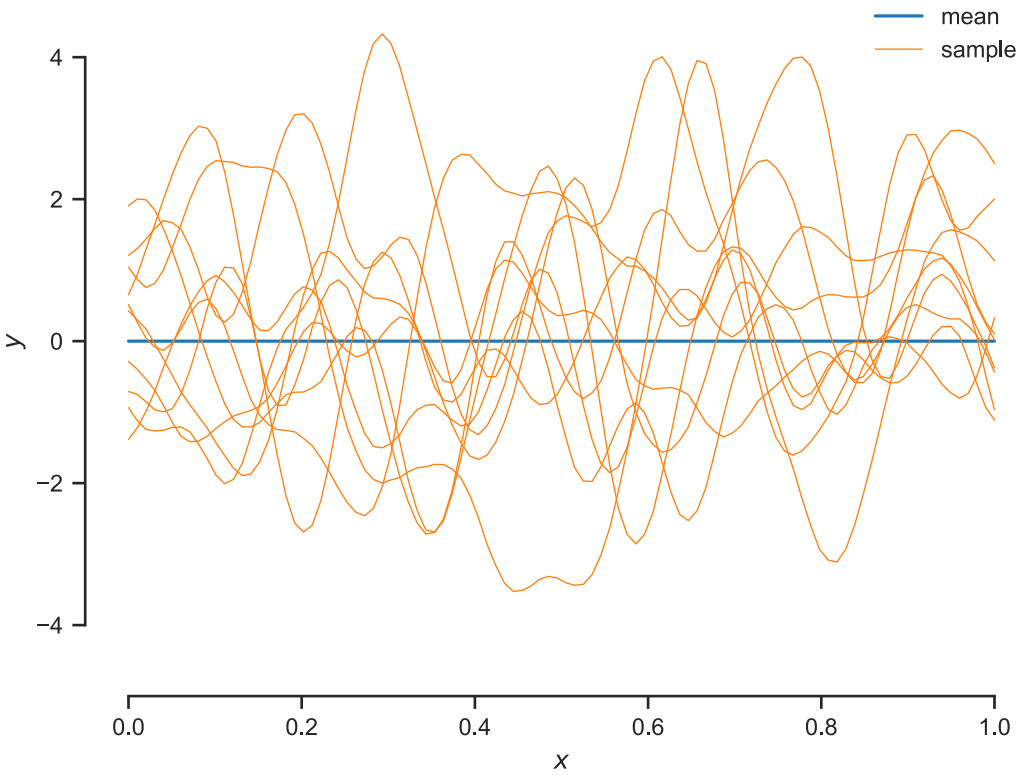
95% probability lies in $\pm 2\sigma$. $3 = 2\sigma$, which becomes $\sigma = \frac{3}{2}$. Then $s^2 = \sigma = (\frac{3}{2})^2$

In [ ]:
```python
# Your code here
import torch
import gpytorch
from gpytorch.kernels import RBFKernel, ScaleKernel

# Define the covariance function
k = ScaleKernel(RBFKernel())
k.outputscale = (3.0/2)**2
k.base_kernel.lengthscale = 0.05

# Define the mean function
mean = gpytorch.means.ConstantMean()
mean.constant = 0.0
```

```
# Sample functions
sample_functions(mean, k, nugget=1e-4)
```



Part C - Continuous function with known length scale

Assume that you hold the following beliefs

- You know that $f(x)$ is continuous, nowhere differentiable.
- You don't know if $f(x)$ has a specific trend.
- You think that $f(x)$ has "wiggles" that are approximately of size $\Delta x = 0.1$.
- You think that $f(x)$ is between -5 and 5.

Hint: Use `gpytorch.kernels.MaternKernel` with $\nu = 1/2$.

Answer:

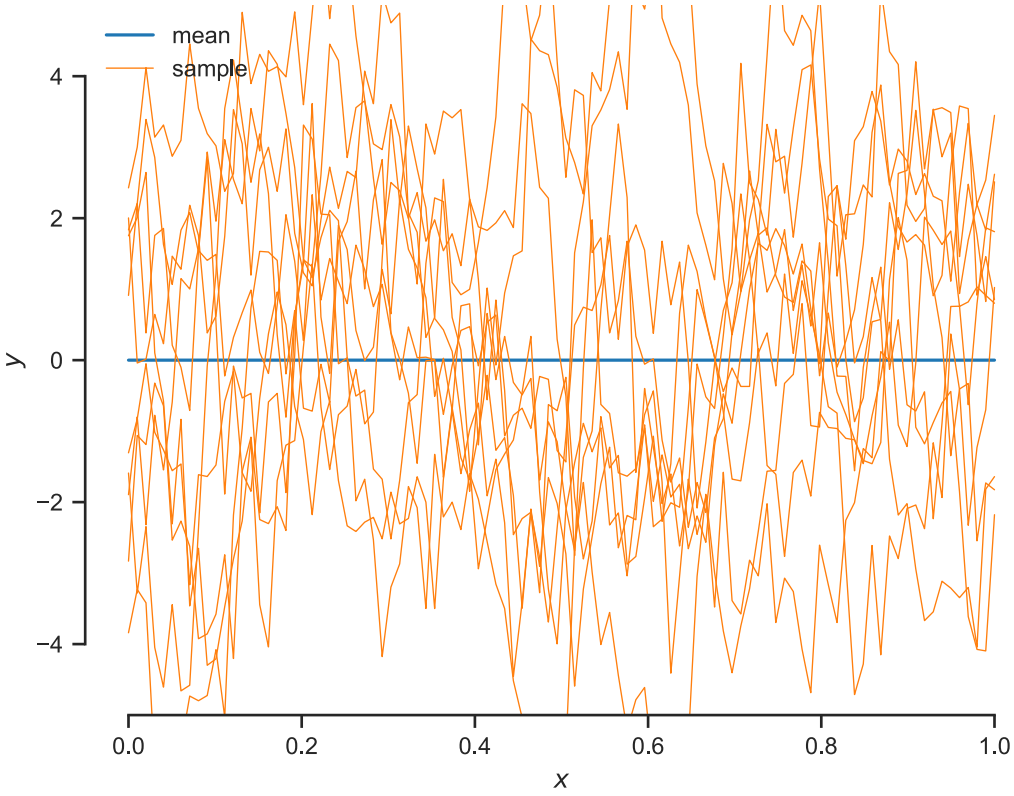
In [ ]:
```
# Your code here
import torch
import gpytorch
from gpytorch.kernels import RBFKernel, ScaleKernel, MaternKernel

# Define the covariance function
k = ScaleKernel(MaternKernel(nu=0.5))
k.outputscale = (5.0/2)**2
k.base_kernel.lengthscale = 0.1

# Define the mean function
mean = gpytorch.means.ConstantMean()
```

```
mean.constant = 0.0

# Sample functions
sample_functions(mean, k, nugget=1e-4)
```



Part D - Smooth periodic function with known length scale

Assume that you hold the following beliefs

- You know that $f(x)$ is smooth.
- You know that $f(x)$ is periodic with period 0.1.
- You don't know if $f(x)$ has a specific trend.
- You think that $f(x)$ has "wiggles" that are approximately of size $\Delta x = 0.5$ of the period.
- You think that $f(x)$ is between -5 and 5.

Hint: Use `gpytorch.kernels.PeriodicKernel`.

Answer:

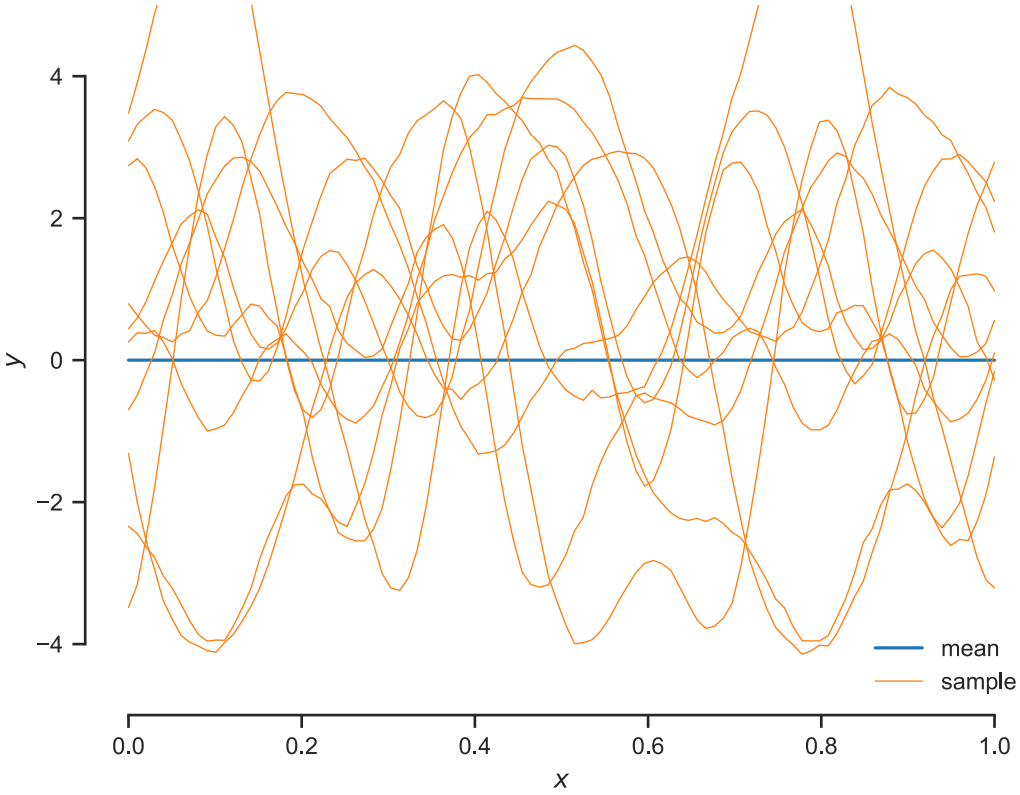
Δx=0.5×period=0.5×0.1=0.05, we set the lengthscale ℓ to 0.05

In [ ]:
```
# Your code here
import torch
import gpytorch
from gpytorch.kernels import RBFKernel, ScaleKernel, MaternKernel, PeriodicKernel
```

```
# Define the covariance function
k = ScaleKernel(PeriodicKernel(period_length=0.1))
k.outputscale = (5.0/2)**2
k.base_kernel.lengthscale = 0.5

# Define the mean function
mean = gpytorch.means.ConstantMean()
mean.constant = 0.0

# Sample functions
sample_functions(mean, k, nugget=1e-3)
```



Part E - Smooth periodic function with known length scale

Assume that you hold the following beliefs

- You know that $f(x)$ is smooth.
- You know that $f(x)$ is periodic with period 0.1.
- You don't know if $f(x)$ has a specific trend.
- You think that $f(x)$ has "wiggles" that are approximately of size $\Delta x = 0.1$ of the period (**the only thing that is different compared to D**).
- You think that $f(x)$ is between -5 and 5.

Hint: Use `gpytorch.kernels.PeriodicKernel`.

Answer:

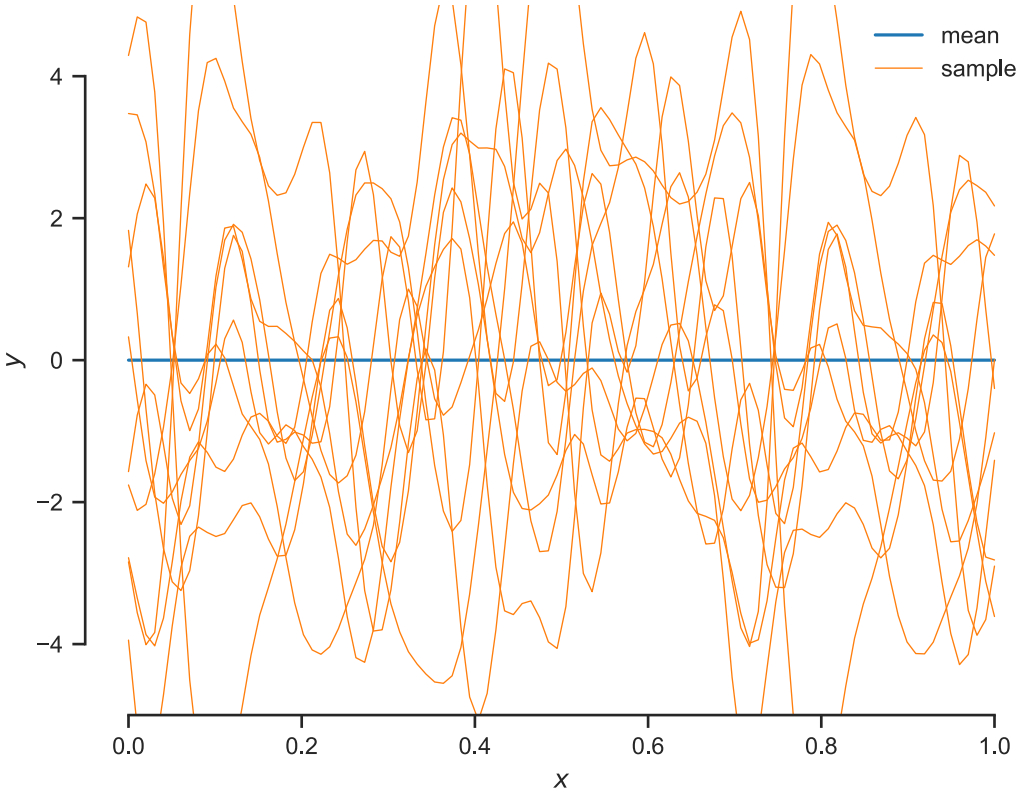
Δx=0.5×period=0.5×0.1=0.05, we set the lengthscale ℓ to 0.05

In [ ]:
```python
# Your code here
import torch
import gpytorch
from gpytorch.kernels import RBFKernel, ScaleKernel, MaternKernel, PeriodicKernel

# Define the covariance function
k = ScaleKernel(PeriodicKernel(period_length=0.1))
k.outputscale = (5.0/2)**2
k.base_kernel.lengthscale = 0.1

# Define the mean function
mean = gpytorch.means.ConstantMean()
mean.constant = 0.0

# Sample functions
sample_functions(mean, k, nugget=1e-4)
```



Part F - The sum of two functions

Assume that you hold the following beliefs

- You know that $f(x) = f_1(x) + f_2(x)$, where:
  - $f_1(x)$ is smooth with variance 2 and length scale 0.5
  - $f_2(x)$ is continuous, nowhere differentiable with variance 0.1 and length scale 0.1

Hint: Use must create a new covariance function that is the sum of two other covariances.

In [ ]:
```python
# Your code here
import torch
import gpytorch
from gpytorch.kernels import RBFKernel, ScaleKernel, MaternKernel, PeriodicKernel

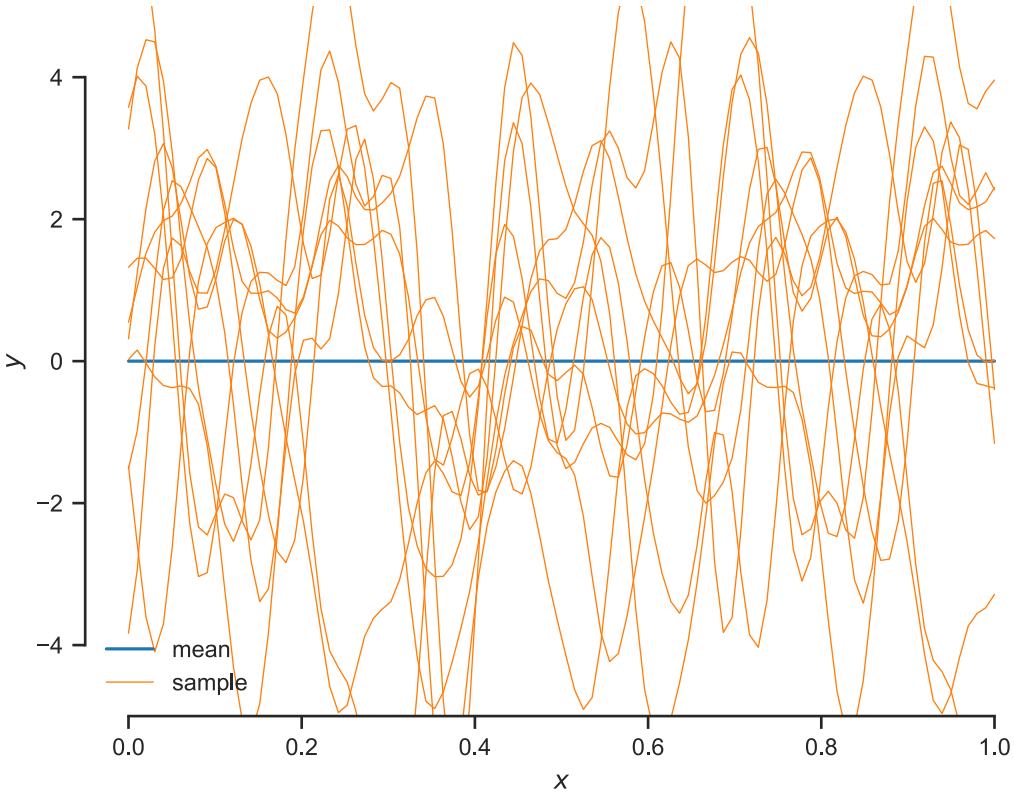
def sum_cov(x1, x2):
    k1 = ScaleKernel(RBFKernel())
    k1.outputscale = 2.0
    k1.base_kernel.lengthscale = 0.5

    k2 = ScaleKernel(MaternKernel(nu=0.5))
    k2.outputscale = 0.1
    k2.base_kernel.lengthscale = 0.1

    cov1 = k1(x1, x2)
    cov2 = k2(x1, x2)
    return ScaleKernel(cov1 + cov2)
```

In [ ]:
```python
# Your code here
import torch
import gpytorch
from gpytorch.kernels import RBFKernel, ScaleKernel, MaternKernel, PeriodicKernel

# Sample functions
sample_functions(mean, sum_cov, nugget=1e-4)
```



Part G - The product of two functions

Assume that you hold the following beliefs

- You know that $f(x) = f_1(x)f_2(x)$, where:
  - $f_1(x)$ is smooth, periodic (period = 0.1), length scale 0.1 (relative to the period), and variance 2.
  - $f_2(x)$ is smooth with length scale 0.5 and variance 1.

Hint: Use must create a new covariance function that is the product of two other covariances.

In [ ]:
```
# Your code here
import torch
import gpytorch
from gpytorch.kernels import RBFKernel, ScaleKernel, MaternKernel, PeriodicKernel

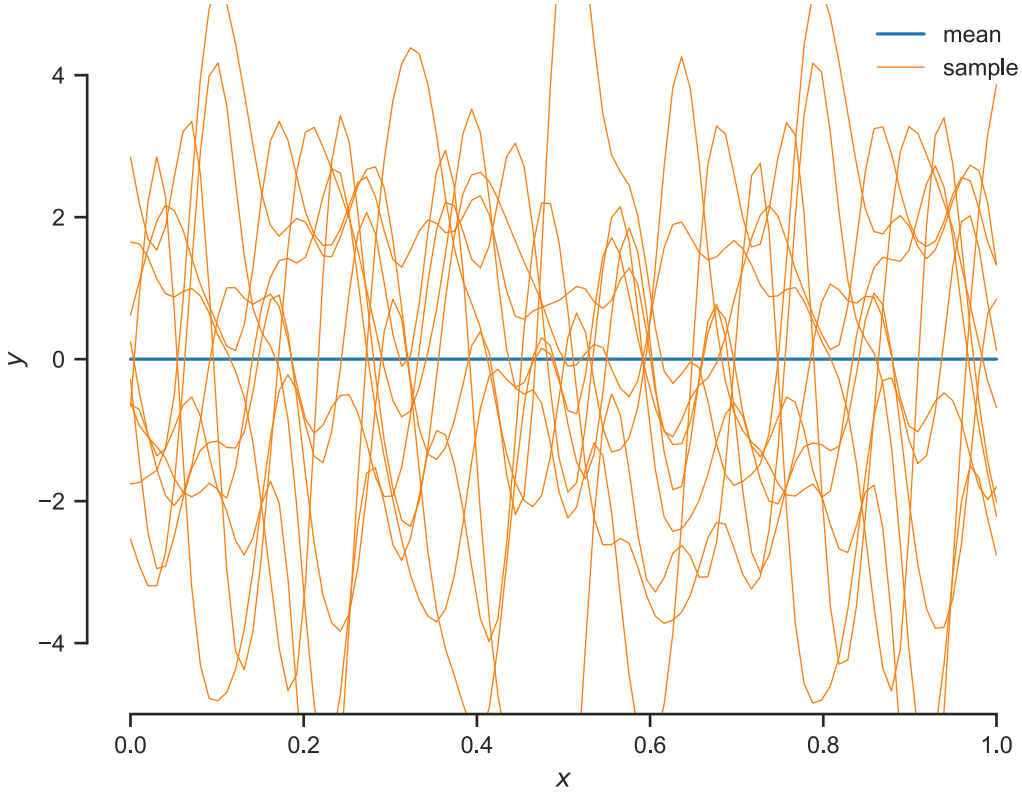
def prod_cov(x1, x2):
    k1 = ScaleKernel(PeriodicKernel(period_length=0.1))
    k1.outputscale = 2.0
    k1.base_kernel.lengthscale = 0.1

    k2 = ScaleKernel(RBFKernel())
    k2.outputscale = 1.0
    k2.base_kernel.lengthscale = 0.5

    cov1 = k1(x1, x2)
    cov2 = k2(x1, x2)
    return ScaleKernel(cov1 * cov2)
```

In [ ]:
```
# Your code here
import torch
import gpytorch
from gpytorch.kernels import RBFKernel, ScaleKernel, MaternKernel, PeriodicKernel

# Sample functions
sample_functions(mean, prod_cov, nugget=1e-4)
```



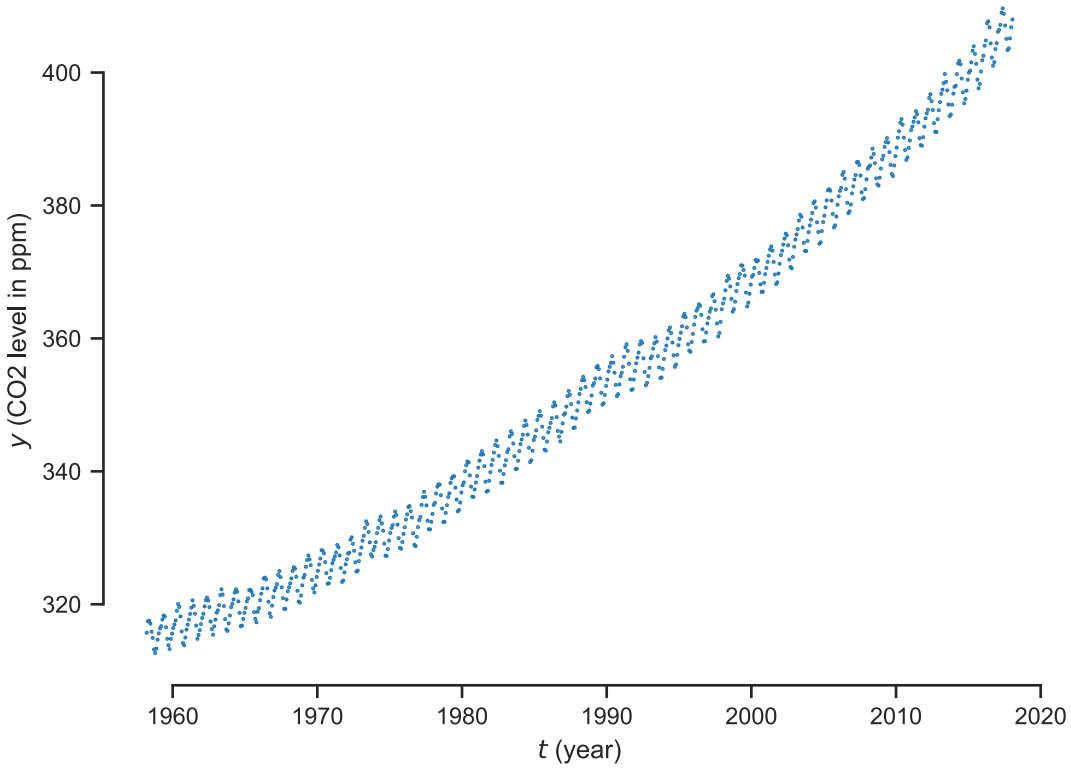
Problem 2

The National Oceanic and Atmospheric Administration (NOAA) has been measuring the levels of atmospheric CO2 at the Mauna Loa, Hawaii. The measurements start in March 1958 and go back to January 2016. The data can be found here. The Python cell below downloads and plots the data set.

In [ ]:
```
url = "https://github.com/PredictiveScienceLab/data-analytics-se/raw/master/lecture
download(url)
```

In [ ]:
```
data = np.loadtxt('mauna_loa_co2.txt')
```

In [ ]:
```
#load data
t = data[:, 2]  #time (in decimal dates)
y = data[:, 4]  #CO2 level (mole fraction in dry air, micromol/mol, abbreviated as
fig, ax = plt.subplots(1, 1)
ax.plot(t, y, '.', markersize=1)
ax.set_xlabel('$t$ (year)')
ax.set_ylabel('$y$ (CO2 level in ppm)')
sns.despine(trim=True);
```



Overall, we observe a steady growth of CO2 levels. The wiggles correspond to seasonal changes. Since most of the population inhabits the northern hemisphere, fuel consumption increases during the northern winters, and CO2 emissions follow. Our goal is to study this dataset with Gaussian process regression. Specifically, we would like to predict the evolution of the CO2 levels from Feb 2018 to Feb 2028 and quantify our uncertainty about this prediction.

Working with a scaled version of the inputs and outputs is always a good idea. We are going to scale the times as follows:

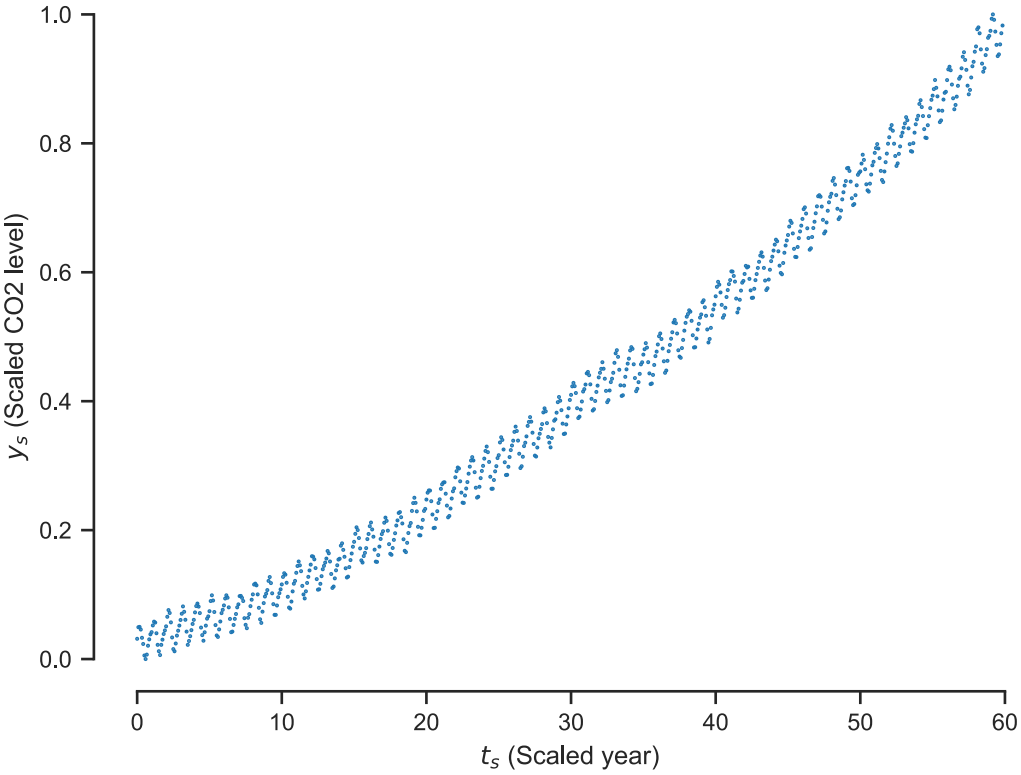
$$t_s = t - t_{\min}.$$

So, time is still in fractional years, but we start counting at zero instead of 1950. We scale the y's as:

$$y_s = \frac{y - y_{\min}}{y_{\max} - y_{\min}}.$$

This takes all the y between 0 and 1. Here is what the scaled data look like:

In [ ]:
```
t_s = t - t.min()
y_s = (y - y.min()) / (y.max() - y.min())
fig, ax = plt.subplots(1, 1)
ax.plot(t_s, y_s, '.', markersize=1)
ax.set_xlabel('$t_s$ (Scaled year)')
ax.set_ylabel('$y_s$ (Scaled CO2 level)')
sns.despine(trim=True);
```



Work with the scaled data in what follows as you develop your model. Scale back to the original units for your final predictions.

Part A - Naive approach

Use a zero mean Gaussian process with a squared exponential covariance function to fit the data and make the required prediction (ten years after the last observation).

Answer:

Again, this is done for you so that you have a concrete example of what is requested.

In [ ]:
```
cov_module = ScaleKernel(RBFKernel())
mean_module = gpytorch.means.ConstantMean()
train_x = torch.from_numpy(t_s).float()
train_y = torch.from_numpy(y_s).float()
naive_model = ExactGP(
    train_x,
    train_y,
    mean_module=mean_module,
    covar_module=cov_module
)
train(naive_model, train_x, train_y)

Notice that the squared exponential covariance captures the long terms but fails to capture the seasonal fluctuations. The seasonal fluctuations are treated as noise. This is wrong. You will have to fix this in the next part.

Part B - Improving the prior covariance

Now, use the ideas of Problem 1 to develop a covariance function that exhibits the following characteristics visible in the data (call $f(x)$ the scaled CO2 level.

- $f(x)$ is smooth.
- $f(x)$ has a clear trend with a multi-year length scale.
- $f(x)$ has seasonal fluctuations with a period of one year.
- $f(x)$ exhibits small fluctuations within its period.

There is more than one correct answer.

Answer:

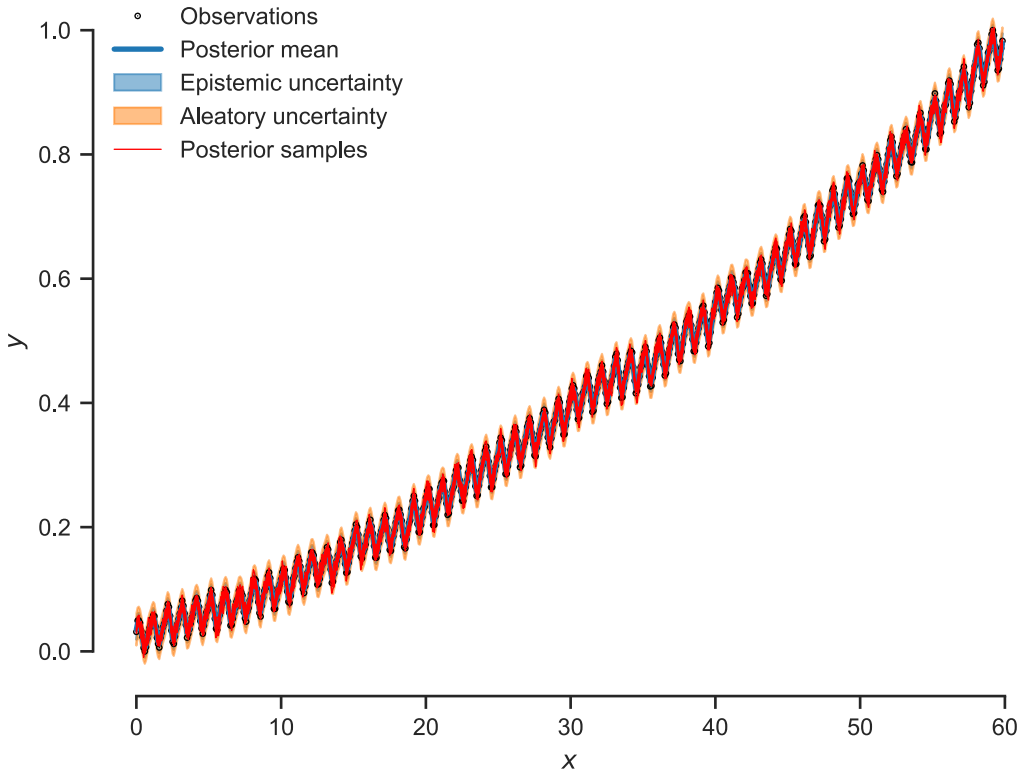
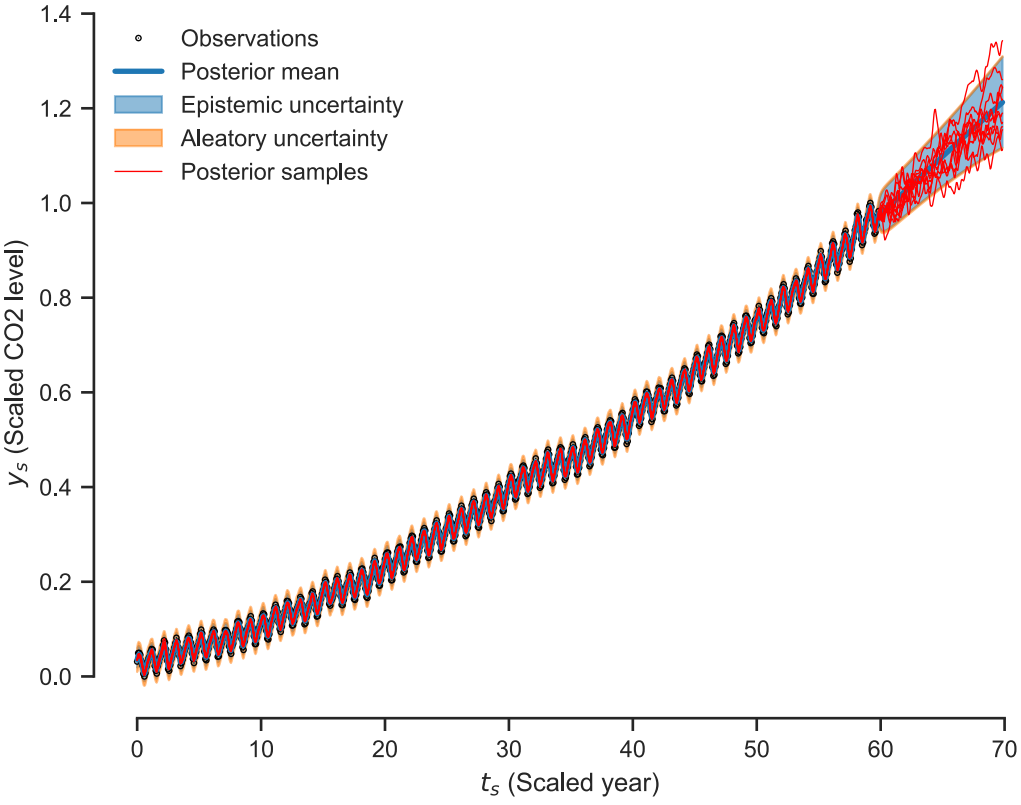
Plot using the following block:

In [ ]:
```
plot_1d_regression(model=model, x_star=train_x);
```

```
x_star = torch.linspace(0, max(train_x)+10, 1200)
plot_1d_regression(model=model, x_star=x_star,
                   xlabel='$t_s$ (Scaled year)', ylabel='$y_s$ (Scaled CO2 level)')
```





Part C - Predicting the future

How does your model predict the future? Why is it better than the naive model?

Answer:

The model I created predicts the future with more characteristics than the naive model, which is the outputs look different. The created model has samples that are more representative of the observations, so the predictions follow similar fluctuations that the observations have. The samples of the predictions of the next 10 years, as mentioned in part A, all show that the scaled CO2 value will continue to rise. The posterior mean shows that the future will begin to show a slower increase, but an increase nonetheless. The created model is better than the naive model, because the naive model is using a covariance module that only includes a RBFKernel, which does not describe the expected characteristics. For instance if you look at the samples on the first graph of both the naive model vs the created model, the created model provides a near exact copy of the observed data. This is why the created model is better than the naive model.

Part D - Bayesian information criterion

As we have seen in earlier lectures, the Bayesian informationc criterion (BIC), see this, can bse used to compare two models. The criterion says that one should:

- fit the models with maximum likelihood,
- and compute the quantity:

$$\mathrm{BIC} = d\ln(n) - 2\ln(\hat{L}),$$

where d is the number of model parameters, and $\hat{L}$ the maximum likelihood.

- pick the model with the smallest BIC.

Use BIC to show that the model you constructed in Part C is indeed better than the naïve model of Part A.

Answer:

In [ ]:
```
# Hint: You can find the parameters of a model like this
list(naive_model.hyperparameters())
```

print(log_like)
```

```
tensor(2.3869, grad_fn=<DivBackward0>)
```

In [ ]:
```
# Hint: The BIC is
bic = -2 * log_like + m * np.log(train_x.shape[0])
print(bic)
```

```
tensor(21.5377, grad_fn=<AddBackward0>)
```

In [ ]:
```
# Your code here
list(model.hyperparameters())
m = sum(p.numel() for p in model.hyperparameters())
print(m)
mll = gpytorch.mlls.ExactMarginalLogLikelihood(model.likelihood, model)
log_like = mll(model(train_x), train_y)
print(log_like)
bic = -2 * log_like + m * np.log(train_x.shape[0])
print(bic)
```

```
10
tensor(3.4263, grad_fn=<DivBackward0>)
tensor(58.9260, grad_fn=<AddBackward0>)
```

The BIC value of the created model is 58.93 and the BIC value of the naive model is 21.54. The difference in the BIC values explains key differences between the models. BIC balances the complexity of the model vs the goodness of fit. Therefore, if the created model is seen as too complex, the BIC will be larger than that of the naive model. This is exactly what is happening in this problem. When I change the model parameters to be simpler, the BIC value stays at about 45.0. Then when I add some complexity to the model, which matches the problem's characteristics and fluctuations, the BIC value increases. This shows the the model is becoming more complex, which keeps the BIC value from becoming lower than the BIC value of the naive model.
